# AUTOMATA AND TRANSCENDENTAL NUMBER THEORY

MICHEL MENDES FRANCE

UNIVERSITE DE BORDEAUX I

## 1. An example.

Let  $E$  be the set of finite sums of distinct powers of 4,

$$E = \{0, 1, 4, 5, 16, \dots\}$$

and let  $2E$  be the set obtained by doubling  $E$

$$2E = \{0, 2, 8, 10, 32, \dots\}$$

Define the real number

$$\alpha = \sum_{n \in E} \frac{1}{2^n} = \sum_{n=0}^{\infty} \frac{\alpha_n}{2^n}.$$

The sequence  $(\alpha_n)$  represents the characteristic function of  $E$ .

The binary expansion of  $\alpha$  is thus "known" in the sense which we make more precise in the last paragraph.

A. Blanchard noticed that the  $1/\alpha$  has a simple binary expansion (1). Indeed,

$$\frac{1}{\alpha} = \frac{1}{2} \times \sum_{n \in 2E} \frac{1}{2^n} .$$

The proof of this is very simple. Let

$$\beta = \frac{2}{\alpha} = \sum_{n \in 2E} \frac{1}{2^n} .$$

Observe

$$\alpha = \prod_{n=0}^{\infty} \left( 1 + \frac{1}{2^{4^n}} \right)$$

$$\beta = \prod_{n=0}^{\infty} \left( 1 + \frac{1}{2^{2 \cdot 4^n}} \right)$$

so that

$$\alpha\beta = \prod_{n=0}^{\infty} \left( 1 + \frac{1}{2^{2^n}} \right) .$$

Using Euler's product formula

$$\prod_{n=0}^{\infty} (1 + x^{2^n}) = (1 - x)^{-1} ,$$

we conclude  $\alpha\beta = 2$  .

Q.E.D.

A careful look at the binary expansion of  $\alpha$  shows that

$\alpha$  is transcendental. To be more precise, one notices in the

expansion of  $\alpha$  long blocks of 0's from which one can deduce

the following theorem.

THEOREM 1: There exists a constant  $c > 0$  such that for infinitely many rational numbers  $a/q$

$$\left| \alpha - \frac{a}{q} \right| < \frac{c}{q^3}.$$

Roth's theorem then shows that  $\alpha$  is indeed transcendental. For details, see (1).

## 2. Formal power series.

We shall give here a new proof of the transcendence of  $\alpha$ .

Let  $\gamma$  be a real number

$$\gamma = \sum_{n=0}^{\infty} \frac{\gamma_n}{2^n}, \quad \gamma_0 = [\gamma], \quad \gamma_n \in \{0, 1\}, \quad n \geq 1.$$

Let  $q = p^\mu$  be a given prime power ( $\mu \geq 1$ ). To  $\gamma$  we associate the formal power series

$$\gamma = \gamma(X) = \sum_{n=0}^{\infty} \gamma_n X^n \in \mathbb{F}_q((X))$$

where the coefficients  $\gamma_n$  are considered as elements of the

finite field  $\mathbb{F}_q$  ( $\gamma_0$  can be given the value  $\gamma_0 \pmod{q}$  for

example). The ring  $\mathbb{F}_q[X]$  of integers in  $\mathbb{F}_q((X))$  is just the

ring of polynomials. The field  $\mathbb{F}_q(X)$  of rational elements in

$F_q((X))$  is the set of  $A/B$ ,  $A \in F_q[X]$ ,  $B \in F_q[X]$ . An element  $\gamma \in F_q((X))$  is said to be algebraic (over  $F_q(X)$ ) if there exist polynomials  $a_v, a_{v-1}, \dots, a_0$  not all zero such that

$$a_0 \gamma^v + a_1 \gamma^{v-1} + \dots + a_{v-1} \gamma + a_v = 0.$$

A nonalgebraic element is transcendental.

THEOREM 2: If an element  $\gamma$  is an irrational algebraic element of some field, it is transcendental in any other field.

This very vague statement needs to be explained. Let

$q' > q$  be another prime power :  $q' = (p')^v$ ,  $p' \neq p$ . Let  $j$  be an injective map

$$F_q \xhookrightarrow{j} F_{q'}.$$

( $j$  is not a field homomorphism :  $j$  is a map defined on the set  $F_q$  and taking values in the set  $F_{q'}$ ). We identify  $F_q$  with a subset of  $F_{q'}$ .

Suppose

$$\gamma = \sum_{n=0}^{\infty} \gamma_n X^n \in F_q((X))$$

is irrational and algebraic over  $F_q(X)$ . The theorem states that  $\gamma$  considered as element of  $F_{q'}((X))$  is transcendental over  $F_{q'}(X)$ . See (2).

This result led J. Loxton and A. van der Poorten (3)

to the deeper result that the real number

$$\gamma = \sum_{n=0}^{\infty} \frac{\gamma_n}{2^n}$$

is transcendental over  $\mathbb{Q}$ .

Keeping this in mind, we turn back to our numbers

$$\alpha = \sum_{n \in E} \frac{1}{2^n} = \sum_{n=0}^{\infty} \frac{\alpha_n}{2^n} \quad (\alpha_n \in \{0,1\})$$

$$\beta = \sum_{n \in 2E} \frac{1}{2^n} = \sum_{n=0}^{\infty} \frac{\beta_n}{2^n} \quad (\beta_n \in \{0,1\}).$$

We consider the two formal power series

$$\alpha = \alpha(X) = \sum_{n=0}^{\infty} \alpha_n X^n = \prod_{n=0}^{\infty} (1 + X^{4^n}) \in \mathbb{F}_2((X))$$

$$\beta = \beta(X) = \sum_{n=0}^{\infty} \beta_n X^n = \prod_{n=0}^{\infty} (1 + X^{2 \cdot 4^n}) \in \mathbb{F}_2((X)).$$

Then

$$\alpha\beta = \prod_{n=0}^{\infty} (1 + X^{2^n}) = (1 - X)^{-1}.$$

Notice also that in  $\mathbb{F}_2((X))$ .

$$\alpha^2 = (\alpha(X))^2 = \alpha(X^2) = \beta$$

hence

$$\alpha^3 = (1 - X)^{-1}$$

which shows that  $\alpha$  is a cubic irrationality in  $\mathbb{F}_2((X))$ .

Loxton and van der Poorten's result then implies the

transcendency of the real number  $\alpha$  .

Q.E.D.

The following conjectures are somehow related to the above discussion:

CONJECTURE 1: Suppose  $\gamma_0, \gamma_1, \gamma_2, \dots$  is an infinite sequence of 0's and 1's, which is not eventually periodic. Prove that one at least of the two numbers

$$\sum_{n=0}^{\infty} \frac{\gamma_n}{2^n}, \quad \sum_{n=0}^{\infty} \frac{\gamma_n}{3^n}$$

is transcendental.

CONJECTURE 2: All the irrational numbers of the Cantor ternary set are transcendental.

### 3. AUTOMATA THEORY

An automaton is a finite set of points (states) with rules indicating how to go from one state to another. For example the automaton  $\mathcal{M}$

$\mathcal{M}$

tells us that if we are given the instructions 1010 we are to leave from the initial state A, then 1 sends us back onto A, 0 onto B, 1 onto C, 0 onto A. Any finite string of 0's 1's will send us onto one of the final states A,B or C.

The definition of the automaton is not yet complete. The states themselves are renamed with the symbols 0 or 1. Say  $A = 1$ ,  $B = 0$ ,  $C = 1$ . Now every finite string of 0's and 1's is sent on 0 or 1.

Look at the sequence of integers as a sequence of words on the symbols 0 and 1

0, 1, 10, 11, 100, 101, 110, 111, 1000,...

The integer 6 for example acts on the automaton  $\mathcal{M}$  as indicated

$$110A = 11B = 1C = A \rightarrow 1$$

hence  $\mathcal{M} : 6 \mapsto \mathcal{M}(6) = 1$ . The infinite sequence

$$\mathcal{M}(0), \mathcal{M}(1), \mathcal{M}(2), \dots, \mathcal{M}(n), \dots$$

is said to be generated by the automaton  $\mathcal{M}$ .

Given an infinite sequence of 0's and 1's, one can ask whether there exists an automaton that generates it. The question is pertinent in that that the family of all 0,1-sequences is noncountable whereas the family of automata is

countable. The following result answers our question and shows the relevance of automata theory to the theory of transcendental numbers.

THEOREM 3: A sequence  $\epsilon = (\epsilon_n)$  of 0's and 1's is generated by automaton if and only if the formal power series

$$\sum_{n=0}^{\infty} \epsilon_n X^n \in F_2((X))$$

is algebraic over  $F_2((X))$ .

( For details, see (2) ).

As a consequence, the digits of  $\alpha$  and those of  $\beta$  are indeed generated by automata.  $A$  generates  $\alpha$  and  $B$  generates  $\beta$

$A = 1$   
 $B = 1$   
 $C = 0$

$A$

$A \rightarrow 1$   
 $B \rightarrow 1$   
 $C \rightarrow 1$   
 $D \rightarrow 0$

$B$

Once one knows the automaton that generates  $\alpha$  ( resp.  $\beta$  ), then one can obtain the millionth digit, say, of  $\alpha$  without having to compute the preceding ones. It is somehow remarkable that both  $\alpha$  and  $1/\alpha$  ( =  $\beta/2$  ) share this property.

Irrational algebraic numbers do not have this property.

Indeed, as noticed by Loxton and van der Poorten, one has the following corollary of theorem 2 .

COROLLARY: The digits of real algebraic irrational numbers are not generated by automata.

Indeed if

$$\epsilon = \sum \frac{\epsilon_n}{2^n}$$

were automata generated, then

$$\sum \epsilon_n X^n$$

would be algebraic over  $\mathbb{F}_2(X)$  hence  $\epsilon$  would be transcendental over  $\mathbb{Q}$  .

This corollary seems to indicate that the knowledge of the millionth digit of  $\sqrt{2}$  involves the knowledge of the nine hundred ninety nine thousand nine hundred ninety ninth digit and of the preceding ones...

## 4. EXERCISES.

1. Let  $E_1$  be the set of integers which do not contain 1 in their expansion in base 4 and let  $E_3$  the set of integers which do not contain 3 in their expansion in base 4. Define

$$\gamma = \sum_{n \in E_3} \frac{1}{2^n} \quad \delta = \frac{1}{4} \sum_{n \in E_1} \frac{1}{2^n}.$$

Prove that  $\gamma\delta = 1$ . Show that  $\gamma$  and  $\delta$  are generated by automata.

2. Write the continued fraction expansion of  $\alpha$ .
